

Day 5

1. Introducing Names

Let's talk about names.

$$\begin{aligned}\mathcal{X} &\ni x \\ \mathcal{V} &\in v ::= z \\ \mathcal{T} &\ni t ::= z \mid t_1 + t_2 \mid t_1 \times t_2 \mid t_1 \div t_2 \mid x \mid \text{let } x = t_1 \text{ in } t_2\end{aligned}$$

As before, we want:

- An evaluation relation
- An approximation of the evaluation relation that guarantees safety.

What are the problems?

- $\frac{}{x \Downarrow ??}$
- $\frac{t_1 \Downarrow v_1 \quad t_2 \Downarrow v_2}{\text{let } x = t_1 \text{ in } t_2 \Downarrow v_2} \dots$ but where did v_1 go?
v1 should go t2 then has v2

2. Substitution

First approach: *substitute* values into terms.

Term 中变量x替换成值v

We define the substitution of a value v for a variable x in a term t (notation $t[v/x]$) as follows:

$$\begin{aligned}y[v/x] &= \begin{cases} v & \text{if } x = y \\ y & \text{otherwise} \end{cases} \\ (t_1 \odot t_2)[v/x] &= t_1[v/x] \odot t_2[v/x] & \odot \in \{+, \times, \div\} \\ (\text{let } y = t_1 \text{ in } t_2)[v/x] &= \begin{cases} \text{let } y = t_1[v/x] \text{ in } t_2 & \text{if } x = y \\ \text{let } y = t_1[v/x] \text{ in } [v/x]t_2 & \text{otherwise} \end{cases}\end{aligned}$$

function + substitution = function application

Relevant points:

- Relying on the inclusion of values in terms $\mathcal{V} \subseteq \mathcal{T}$. Could introduce explicit notation for this, but not even I am that pedantic.
- Shadowing of variables in **let**. (Intuition: bound names don't matter. Will pay off momentarily.)

let body中的变量是shadow, 意味着与外面相同变量名字=》不会互相影响

Now, we are equipped to give our first meaning of variables and **let**:

$$\frac{t_1 \Downarrow v_1 \quad t_2[v_1/x] \Downarrow v_2}{\text{let } x = t_1 \text{ in } t_2 \Downarrow v_2}$$

- Substitution is a **meta-theoretic** notion: we don't have separate evaluation rules for $x[4/x]$ and 4, we treat those as the same term.

No rule for variables:

$$\frac{\frac{4 \Downarrow 4}{\text{let } x = 4 \text{ in } x \div x \Downarrow 1} \quad \frac{\frac{4 \Downarrow 4}{4 \div 4 \Downarrow 1} \quad \frac{4 \Downarrow 4}{4 \Downarrow 4}}{4 \div 4 \Downarrow 1} \quad \text{variable 限制}$$

So variables are always stuck terms: no derivation for $\text{let } x = 5 \text{ in } y \Downarrow z$ for any z .

3. α -Equivalence

Intuition: **changing the names of local variables doesn't matter**. Now, we're in a position to capture this idea formally. **local variables 名字不影响 substitute**

We define α -equivalence—i.e., **equivalence up to renaming of variables**—by:

$$\begin{array}{c} \frac{}{x \equiv_{\alpha} x} \quad \frac{}{z \equiv_{\alpha} z} \quad \frac{t_1 \equiv_{\alpha} t'_1 \quad t_2 \equiv_{\alpha} t'_2}{t_1 \odot t_2 \equiv_{\alpha} t'_1 \odot t'_2} \quad (\odot \in \{+, \times, \div\}) \\ \frac{t_1 \equiv_{\alpha} t'_1 \quad t_2[z/x] \equiv_{\alpha} t'_2[z/y]}{\text{let } x = t_1 \text{ in } t_2 \equiv_{\alpha} \text{let } y = t'_1 \text{ in } t'_2} \quad (z \notin \text{fv}(t_1) \cup \text{fv}(t_2)) \end{array}$$

where the **free variables** of a term are intuitively those variables in the term not defined by an enclosing **let** statement:

$$\begin{array}{ll} \text{fv}(x) = \{x\} & \text{fv}(t_1 \odot t_2) = \text{fv}(t_1) \cup \text{fv}(t_2), \quad \odot \in \{+, \times, \div\} \\ \text{fv}(z) = \emptyset & \text{fv}(\text{let } x = t_1 \text{ in } t_2) = \text{fv}(t_1) \cup (\text{fv}(t_2) \setminus \{x\}) \end{array}$$

Why do we need a new (also called “fresh”) variable in the **let** case? **Mostly to avoid the possibility that x is already used in t'_2 .**

Now we can make formal our intuition about α -equivalence:

Theorem. *If $t \equiv_{\alpha} t'$ and $t \Downarrow v$ then $t' \Downarrow v$.*

Proof. By structural induction on the derivation of $t \equiv_{\alpha} t'$:

- Case $\frac{}{x \equiv_{\alpha} x}$: the second hypothesis ($x \Downarrow v$) is impossible.
- Case $\frac{}{z \equiv_{\alpha} z}$: by definition of \Downarrow .
- Case $\frac{t_1 \equiv_{\alpha} t'_1 \quad t_2 \equiv_{\alpha} t'_2}{t_1 \odot t'_1 \equiv_{\alpha} t_2 \odot t'_2}$: If $t \Downarrow v$, then we have that $t_1 \Downarrow v_1$, $t_2 \Downarrow v_2$, and (abusing notation slightly) $v = v_1 \odot v_2$. Now, by the induction hypothesis, $t'_1 \Downarrow v_1$, $t'_2 \Downarrow v_2$, and finally by the definition of \Downarrow we have $t' \Downarrow v$.

- Case $\frac{t_1 \equiv_\alpha t'_1 \quad [z/x]t_2 \equiv_\alpha [z/y]t'_2}{\text{let } x = t_1 \text{ in } t_2 \equiv_\alpha \text{let } y = t'_1 \text{ in } t'_2}$: By the induction hypothesis applied to the first subderivation we have $t_1 \Downarrow v_1$, $t'_1 \Downarrow v_1$. Similarly, by the IH applied to the second subderivation, we have $t_2[z/x][v_1/z] \Downarrow v_2$ and $t'_2[z/y][v_1/z] \Downarrow v_2$. But the latter two expressions are equivalent (by tedious lemma) to $t_2[v_1/x]$ and $t'_2[v_1/y]$, so we have that the original terms evaluate to v_2 as well. \square
